The coelom is the main body cavity in most animals and is positioned inside the body to surround and contain the digestive tract and other organs. In some animals, it is lined with mesothelium. In other animals, such as molluscs, it remains undifferentiated. In the past, and for practical purposes, coelom characteristics have been used to classify bilaterian animal phyla into informal groups.

Invertebrate chordates are diverse but share many common characteristics. These organisms reside in marine environments living individually or in colonies. Invertebrate chordates feed on tiny organic matter, such as plankton, suspended in the water. Invertebrate chordates are coelomates or animals with a true body cavity.

Two major lines of more complex animals were derived from the coelomates: the protostomes, which became the higher invertebrates, and the deuterostomes, which eventually gave rise to the vertebrates. About 650 million years ago, the annelids (segmented worms) evolved from a protostome ancestor, followed about 50 million years later by the molluscs (clams, snails, mussels, squid, octopus).
